Quantum chaos meets quantum channels

September 13, 2024

1 Model

The spin chain we are interested in studying first is that studied by Mirkin and Wisniacki in Ref. [1]:

$$H = \sum_{i=1}^{L} \left(h_x \sigma_i^x + h_z \sigma_i^z \right) - \sum_{i=1}^{L-1} J_z \sigma_i^z \sigma_{i+1}^z. \tag{1}$$

2 Mean level spacing ratio

The level spacing ratio $\tilde{r}_n$ is defined as:

$$\tilde{r}_n = \frac{\min(s_n, s_{n-1})}{\max(s_n, s_{n-1})}, \tag{2}$$

where $s_n = E_{n+1} - E_n$. The mean level spacing ratio $\langle \tilde{r}_n \rangle$ is known to attain the value $\langle \tilde{r}_n \rangle \approx 0.5207$ when the level spacing distribution $P(s)$ is Wigner-Dyson and $\langle \tilde{r}_n \rangle \approx 0.386$ when it is Poisson.

3 Spectral form factor

The spectral form factor $K(t)$ is defined as:

$$K(t) = \frac{1}{2^L} \left\langle |\text{Tr}\, U(t)|^2 \right\rangle = \frac{1}{2^L} \left\langle \sum_{i,j} e^{i(E_i - E_j)t} \right\rangle, \tag{3}$$

where $\langle \cdot \rangle$ denotes the ensemble-average over statistically-similar systems.

4 Chaometer's quantum channel

The reduced dyanmics of the chaometer is described by the quantum channel:

$$\mathcal{E}(\rho) = \text{Tr}_E \left(e^{-iHt} \rho \otimes \left| \psi_0^{(E)} \right\rangle \left\langle \psi_0^{(E)} \right| e^{iHt} \right), \tag{4}$$

where H is that of eq. (1), $\left| \psi_0^{(E)} \right\rangle$ the initial state of all spins except the chaometer, and ρ the initial state of the chaometer.

The chaometer's quantum channel $\mathcal{E}$, in general, is divisible into:

1. A unitary operation rotating the Bloch's sphere.

2. A quantum channel that deforms the Bloch's sphere and translates its origin.

Both operations do not commute.

JA: Comentar solución de los estados aleatorios.

Figure 1: Mean level spacing ratio $\langle \tilde{r}_n \rangle$ [c.f. eq. (2)] of the Ising chain with Hamiltonian (1) as a function of ratios h_z/h_x and J/h_x. We assume $J_z = J \, \forall \, k$.
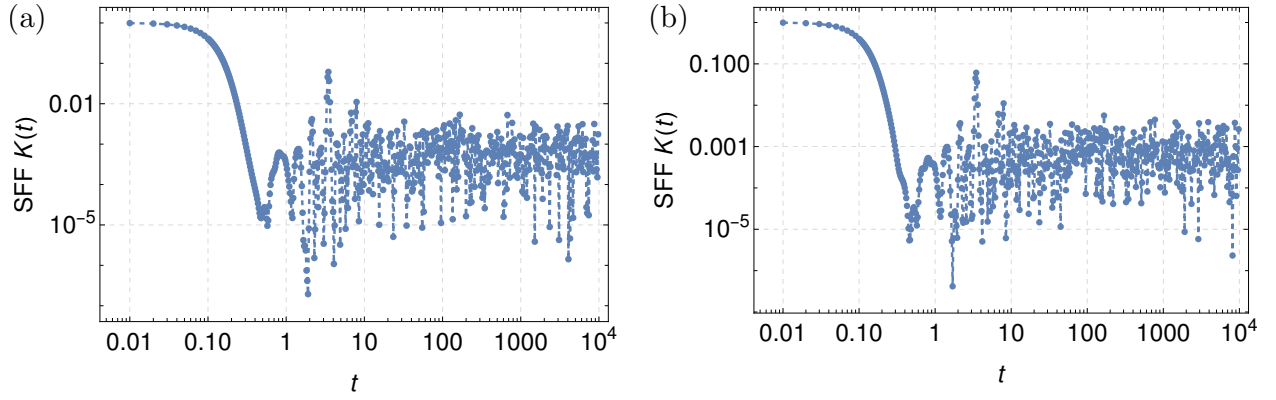

Figure 2: Spectral form factor (SFF) [c.f. (3)] in regular region: $h_z/h_x = 2.5$ and $J/h_x = 1$. **(a)** Whole spectrum. **(b)** Even-parity subspace spectrum.

Figure 3: Spectral form factor (SFF) [c.f. (3)] in chaotic region: $h_z/h_x = 0.5$ and $J/h_x = 1$. **(a)** Whole spectrum. **(b)** Even-parity subspace spectrum.

fig:sff:chaotic

5   Purity of the chaometer

Averaged purity $\mathcal{P}$ is defined in Ref. [1] as:

eq:avg:purity
$$\overline{\mathcal{P}} = \frac{1}{N} \sum_{i=1}^{N} \left(\frac{1}{T} \int_0^T \mathrm{Tr}\left[\rho_i^2(t) \right] \right) \tag{5}$$

where:

- $\rho_i(t)$: chaometer's density matrix.

- N: number of different random initial states of the whole chain. $N = 50$ in Mirkin and Wisniacki [1].

- T: maximum time. $T = 50$ in Mirkin and Wisniacki [1].

.

Also, the normalized averaged purity is defined as

eq:avg:norm:purity
$$\overline{P}_{Norm} = \frac{\overline{P} - \min(\overline{P})}{\max(\overline{P}) - \min(\overline{P})}, \tag{6}$$

where $\max(\overline{P})$ and $\min(\overline{P})$ are the minimum and maximum value obtained when sweeping the parameter range (h_z in their case).

In Fig. 4 we plot one realization of the dynamics of purity of the chaometer. We compare in Fig. 5 our results and those of Mirkin and Wisniacki [1].

6   Purity of Choi-Jamiołkowski matrix

We investigate the purity of Choi-Jamiołkowski matrix of quantum channel $\mathcal{E}(t)$ of the chaometer [c.f. eq. (4)] in Fig. 6.

To compute the Choi-Jamiołkowski matrix $\mathcal{D}(t)$ of the chaometer's quantum channel in eq. (4) we use the definition $(\mathcal{E} \otimes \mathbb{1})[|\phi^+\rangle\langle\phi^+|]$, with $|\phi^+\rangle = 1/\sqrt{2}(|0,0\rangle + |1,1\rangle)$ is the maximally entangled state between two spins, and obtain

eq:choi:chaometer
$$\mathcal{D}(t) = \frac{1}{2} \sum_{i,j,p,q} \langle j, \psi_{0E}| U^\dagger(t)(|p\rangle\langle q| \otimes \mathbb{1}_E)U(t) |i, \psi_{0E}\rangle |q, i\rangle\langle p, j|. \tag{7}$$

fig:purity:one:realization

Figure 5: Averaged $\overline{P}$ and averaged normalized purities $\overline{P}_{Norm}$ [c.f. eqs. (5) and (6).] for $N = 50$ random initial states of the chaometer for each quantum channel showed in the videos. JA: Tendría más sentido sacar la pureza del canal. Lo pienso Taken and modified from Ref. [1].
fig:mirkin2021:fig2:modified

Figure 6: Purity of Choi-Jamiołkowski matrix in (a) regular ($h_z = 2.5$) and (b) chaotic ($h_z = 0.5$) for the three random initial states showed in the video.

Let us write $\mathcal{E}(\rho)$ in computational basis. From eq. (4) we write

$$\mathcal{E}(\rho) = \sum_{k,l} e^{-i(E_k - E_l)t} \langle E_k| (\rho \otimes |\psi_E\rangle\langle\psi_E|) |E_l\rangle \, \mathrm{Tr}_E \left(|E_k\rangle\langle E_l|\right) \tag{8}$$

$$= \sum_{k,l,p,p',\vec{q},\vec{q}'} e^{-i(E_k - E_l)t} \langle E_k| (\rho \otimes |\psi_E\rangle\langle\psi_E|) |E_l\rangle \, \mathrm{Tr}_E \left(|p,\vec{q}\rangle \langle p,\vec{q}|E_k\rangle \langle E_l|p',\vec{q}'\rangle \langle p',\vec{q}'|\right), \tag{9}$$

where $\vec{q}$ and $\vec{q}'$ are indices of elements of the basis of the environment,

$$= \sum_{p,p',\vec{q}} \langle p,\vec{q}| U(t)(\rho \otimes |\psi_E\rangle\langle\psi_E|)U^\dagger(t) |p',\vec{q}\rangle \, |p\rangle\langle p'| \tag{10}$$

$$= \sum_{p,p'} \langle p| \, \mathrm{Tr}_E[U(t)(\rho \otimes |\psi_E\rangle\langle\psi_E|)U^\dagger(t)] \, |p'\rangle \, |p\rangle\langle p'| \, . \tag{11}$$

To compute the Choi-Jamiołkowski matrix $\mathcal{D}(t)$ of the chaometer's quantum channel in eq. (4) we use the definition $(\mathcal{E} \otimes \mathbb{1})[|\phi^+\rangle\langle\phi^+|]$, with $|\phi^+\rangle = 1/\sqrt{2}(|0,0\rangle + |1,1\rangle)$ is the maximally entangled state between two spins, and eq. (11) to obtain

$$\mathcal{D}(t) = \frac{1}{2} \sum_{i,j,p,p',\vec{q}} \langle p,\vec{q}| U(t)(|i,\psi_E\rangle\langle j,\psi_E|)U^\dagger(t) |p',\vec{q}\rangle \, |p,i\rangle\langle p',j| \tag{12}$$

$$= \frac{1}{2} \sum_{i,j,p,p'} \langle j,\psi_{0E}| U^\dagger(t)(|p'\rangle\langle p| \otimes \mathbb{1}_E)U(t) |i,\psi_{0E}\rangle \, |p,i\rangle\langle p',j| \, , \tag{13}$$

₄₃ where we have only reordered the factors and used the resolution of identity over $\mathcal{H}_E$.

We compute the purity of $\mathcal{D}(t)$. From eq. (7) it is straightforward to obtain

$$\mathrm{Tr}\left[\mathcal{D}^2(t)\right] = \frac{1}{4} \sum_{i,j,p,q} \left| \langle i,\psi_{0E}| U^\dagger(t) \left(|p\rangle\langle q| \otimes \mathbb{1}_E\right)U(t)|j,\psi_{0E}\rangle \right|^2 . \tag{14}$$

Moreover, reordering this expression an interesting interpretation of the purity of the Choi-Jamiołkowski matrix is revealed. Let us conveniently rewrite eq. (14) as

$$\mathrm{Tr}\left[\mathcal{D}^2(t)\right] = \sum_i \langle i,\psi_{0E}| U^\dagger(t) \sum_{p,q} \left[\left(\frac{|p\rangle\langle q|}{\sqrt{2}} \otimes \mathbb{1}_E\right)U(t)\left(\frac{\mathbb{1}_S}{2} \otimes |\psi_{0E}\rangle\langle\psi_{0E}|\right)U^\dagger(t)\left(\frac{|q\rangle\langle p|}{\sqrt{2}} \otimes \mathbb{1}_E\right)\right]U(t) |i,\psi_{0E}\rangle .$$

$$\tag{15}$$

₄₄ In other words, the purity of $\mathcal{D}(t)$ represents the probability that the environment remains in its initial state
₄₅ after the following process: First, the system and environment are initialized in a product state, with the
₄₆ system in a maximally mixed state. Next, the combined system evolves. Then, a completely depolarizing
₄₇ channel is applied to the system. Finally, the system and environment undergo reverse evolution.

Figure 7: Most negative eigenvalue $\tilde{\lambda}$ of map $\Lambda(t,s)/2$, with $s = 0.1$ [c.f. eqs. (16) and (17)]. *fig:lambda.tilde(Choi-"jami-"*

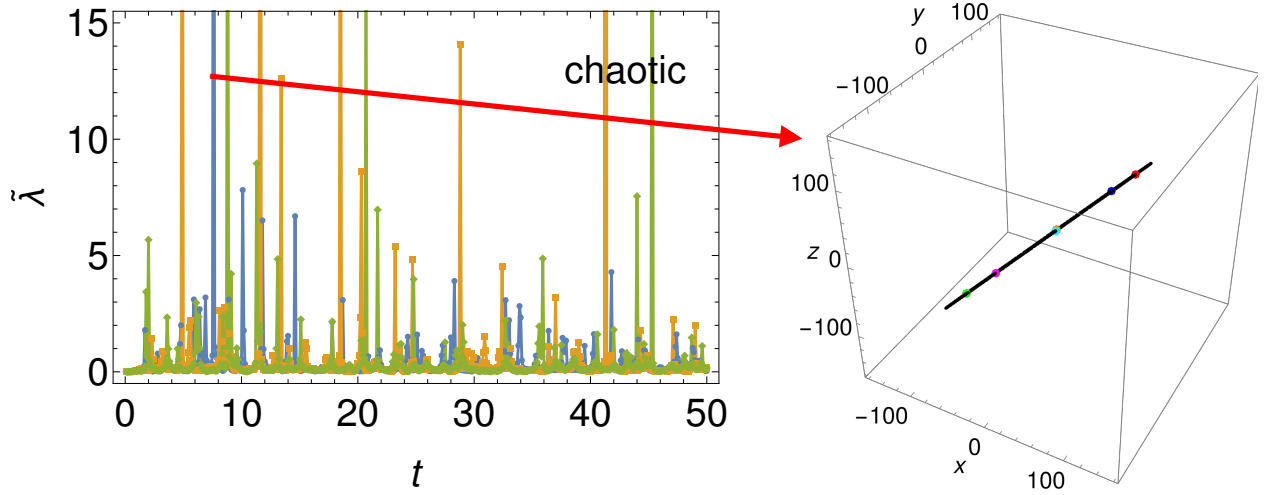

Figure 8: Burst of the Bloch sphere at $t = 0.5$ s.   *fig:burst*

7 Non complete positiveness of $\Lambda(t,s)$

Any quantum channel $\mathcal{E}(t)$ can composed as   *eq:Lambda*

$$\mathcal{E}(t) = \Lambda(t,s) \circ \mathcal{E}(s,0), \qquad (16)$$

nonetheless, $\Lambda(t,s)$ is not in general completely positive. A way to quantify how far is $\Lambda(t,s)$ from being completely positive is through $\tilde{\lambda}$:   *eq:lambda:tilde*

$$\tilde{\lambda} = |\min(0, \lambda_{\mathrm{smallest}})|, \qquad (17)$$

where $\lambda_{\mathrm{smallest}}$ is the smallest eigenvalue of $\Lambda^R(t,s)/2$. We have added the factor $1/2$ just so $\mathrm{Tr}\left[\Lambda^R(t,s)/2\right] = 1$.

Let us fix $s = 0.1$ and investigate the complete positiviness of $\Lambda(t,s)$, see Fig. 7.

8 Purity of Choi-Jamiołkowski matrix of a U from COE
